

Website speed and accessibility review: before improvements

www.atsdiamondtools.co.uk · measured 24 September 2026 · prepared by Red Frog Studio

We ran Google's page speed test (the same one behind PageSpeed Insights) on three key pages of the live site, on both a mobile phone and a desktop computer. This report explains what the scores mean, what is holding the site back, and what we plan to change. A second report will follow once the work is done so the two can be compared side by side.

Scores

Page	Device	Performance	Accessibility	Best practices	SEO
Home page	Mobile	43	80	100	92
	Desktop	97	84	100	92
Category page (Polishing)	Mobile	56	81	100	100
	Desktop	96	84	100	100
Product page (100mm 3-step polishing pads)	Mobile	37	86	75	100
	Desktop	87	90	74	100

Scores are out of 100. 90 to 100 good 50 to 89 needs work 0 to 49 poor

The short version

On a desktop the site is already quick. On a phone it is slow to show its main picture and the page jumps about while it loads. Google now judges sites mainly on the mobile experience, so this is where the effort should go. Accessibility (how well the site works for people using screen readers or with poorer eyesight) is in the amber zone on every page, and the fixes there are small.

What is slowing the mobile site down

- **The main banner picture loads last.** The site's caching plugin treats the big picture at the top of the home page and category pages as if it were further down the page, so the phone does not start fetching it until everything else has arrived. This is the single biggest reason the home page takes over 6 seconds to show its main content on a phone.
- **Phones download desktop-sized pictures.** The banner pictures are sent at up to 2400 pixels wide (around 220 KB each) to screens that only need about half that. The category banner is sent at 3840 pixels wide.

- **Facebook and Google tracking tie up the phone.** The Meta Pixel and Google tags start running the moment the page opens and block the phone for roughly a second before it can respond to taps. Together they account for about 800 milliseconds of the delay on the home page and 1,000 milliseconds on product pages.
- **The logo loads late and pushes the page down.** The header logo is also treated as a "load later" picture, so when it arrives the whole page shifts. This is the main cause of the layout jumps Google measures on every page.
- **Browser caching is switched off for pictures, scripts and styles.** When a visitor moves from one page to the next, their phone downloads the same logo, fonts and scripts again instead of reusing them. This is a hosting setting rather than a website change.
- **Product pages load Apple Pay and Google Pay code up front.** The payment buttons on product pages pull in a large amount of code. It is a useful feature, so we will keep it, but it caps how high the product page score can go.

Accessibility issues found

- The banner's next, previous and dot buttons have no names, so a screen reader announces them as "button".
- The grey "Reviews" count under the star ratings is too faint against the white background to meet the contrast standard.
- The "Visit shop" basket button is icon-only on phones and has no text for screen readers.
- A link in the footer newsletter text is only distinguishable by colour, and it currently points nowhere.
- The clearance offers pop-up has no name for assistive technology, and the product carousels use a list structure that screen readers cannot interpret correctly.
- One "Read more" style link on the home page does not say where it goes.

What we will do

- Load the banner picture and logo straight away, and tell the phone to fetch the banner first.
- Send smaller banner pictures to phones and compress the large versions harder without a visible difference.
- Hold the Facebook and Google tracking scripts back until the page has finished drawing. Nothing is lost: page views and sales are still recorded, just a fraction of a second later.
- Reserve space for pictures so the page does not jump while loading.
- Fix each accessibility issue listed above.
- Ask the hosting provider (Plesk control panel) to switch on browser caching for pictures, scripts and styles. We will supply the exact setting.

A note on the numbers

These scores come from a simulated slow 4G phone connection, which is how Google tests every site. Scores move by a few points from one run to the next, so a change of 3 to 5 points is noise. We test the same three pages, on the same settings, before and after so the comparison is fair.
